2. Chromospheric heating and dynamics

A modeler's perspective on UV bursts

Sanja Danilovic¹

¹ *Institute for Solar Physics, Stockholm University, AlbaNova University Centre, Stockholm, Sweden*

UV bursts are small, intense, transient brightenings visible in ultraviolet images of solar active regions. They are usually associated with small-scale flux cancellation in emerging flux regions, moving magnetic features in sunspot moats, but also sunspot light bridges. They show complex spectral signatures that also indicate that the underlying process might be magnetic reconnection taking place in the lower solar atmosphere. In this talk, I will review some the efforts to model these features and try to identify the requirements that have to met in order to reduce or eliminate current discrepancies between models and observations.

A modeler's perspective on UV bursts

Definition

“ultraviolet (UV) burst”

observed in UV wavelength
range 465-1550 Å

the brief duration of the
brightening event

Definition

“ultraviolet (UV) burst”

observed in UV wavelength range 465-1550 Å

the brief duration of the brightening event

Properties:

- Compactness - core brightenings < 2 arcsec in size; can have extended flame like morphology
- Duration - lifetimes ranging from tens of seconds to over an hour; flickering, recurrent
- Intensity - significantly brighter than the surroundings; Si IV lines enhanced by factor ~ 1000
- Motion - short distance with velocities ≤ 10 km/s; track photospheric magnetic features
- Location - emerging active regions, MMF, light bridges - not directly connected with flares

What are UV bursts?

Intro

Small, but important

- Underlying process – magnetic reconnection
- Challenge for all our current models

Observational constraints

		UV burst		
Observables	EB		FAF	IB
Halp α , H β	Moustache, flame-like morphology		jet like morphology	moustache in 10-20% cases
Na I D2	non-visible			
Mg I b2	non-visible			
Ca II H& K	Moustache, flame-like morphology			
Ca II 8542	Moustache, flame-like morphology			
AIA 1600, 1700	bright		bright	bright
AIA hot channels	non-visible		bright	
Mg II h& K	enhanced, sometimes self-reversal			enhanced, broad
Mg II triplet	in emission, correlates with Halp α			
C II 1330			multiple components	double component
Si IV 1400	enhanced, sometimes self-reversal	enhanced, narrow		wide, triangular shape, Ni II blends
O IV 1400				low Si IV/O IV
He I D3 He I 10830	emission component

Quick overview

Modeling experiments

- One- and two-dimensional models – temperature bump somewhere in the lower atmosphere – Kitai (1983), Berlicki et al. (2010), Berlicki and Heinzel (2014), Grubecka et al. (2016), Fang et al. (2017), Bello Gonzalez et al. (2013), Hong et al. (2017), Reid et al. 2017

- Putting T increase too low results in too high continuum I
- T increase from few 100 to few 1000 K fits chromospheric lines
- Fitting Si IV results in inconsistent chromospheric signatures see Gregal Vissers talk!

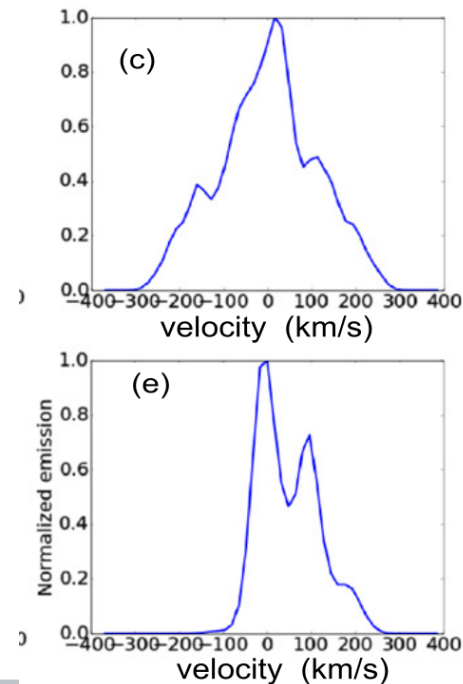

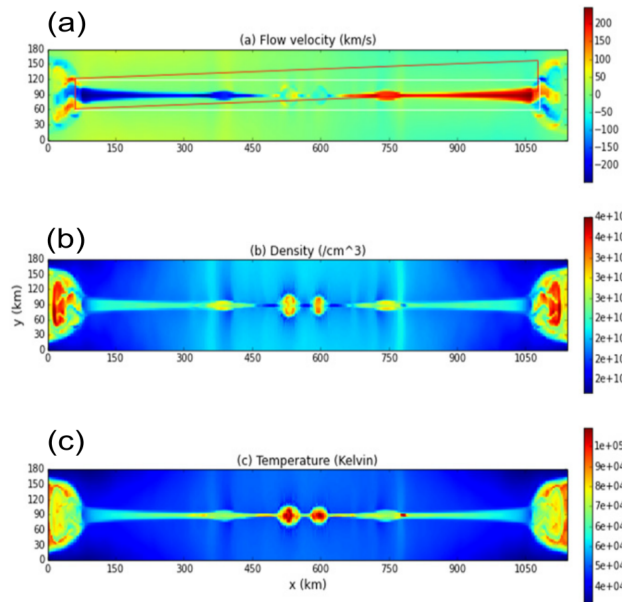

Kitai 1983
