Statistical description of a plasma

- The complete statistic description of a system with N particles is given by the distribution function
  \[ F(x_1, x_2, \ldots, x_N, v_1, v_2, \ldots, v_N, t) \]
  \[ \int F \, dx_1, dx_2, \ldots, dx_N, dv_1, dv_2, \ldots, dv_N = 1 \]

- Hyperspace for N particles has dimension 6 N + 1
- N is typically very large (For Sun: \( N \approx 10^{57} \))

=> No chance to compute or estimate F

Liouville Equation

after Joseph Liouville 1809-1889

The many body distribution

\[ F(x_1, x_2, \ldots, x_N, v_1, v_2, \ldots, v_N, t) \]

obeys the Liouville equation

\[
\frac{\partial F}{\partial t} + \sum_i \left( \frac{\partial F}{\partial x_i} \cdot v_i + \frac{\partial F}{\partial v_i} \cdot a_i^T \right) = 0
\]

\( a_i^T \) acceleration of particle i due to external and interparticle forces

Phase space

Six-dimensional phase space with coordinates axes \( x \) and \( v \) and volume element \( dx dv \)

Many particles (i=1, N) having time-dependent position \( x(t) \) and velocity \( v(t) \). The particle path at subsequent times \( t_1, \ldots, t_N \) is a curve in phase space

Maxwellian velocity distribution function

The general equilibrium VDF in a uniform thermal plasma is the Maxwellian (Gaussian) distribution.

The average velocity spread (variance) is, \( \sigma_v = \sqrt{\frac{2k_B T}{m}} \), and the mean drift velocity, \( v_0 \).

\[
f(v) = n \left( \frac{m}{2\pi k_B T} \right)^{3/2} \exp \left( -\frac{m(v - v_0)^2}{2k_B T} \right)
\]
Anisotropic model velocity distributions

The most common anisotropic VDF in a uniform thermal plasma is the bi-Maxwellian distribution. Left figure shows a sketch of it, with $T_\parallel > T_\perp$.

$$f(v_\perp, v_\parallel) = \frac{n}{T_\perp T_\parallel^{3/2}} \left( \frac{m}{2\pi k_B} \right)^{3/2} \exp \left( -\frac{m v_\perp^2}{2 k_B T_\perp} - \frac{m v_\parallel^2}{2 k_B T_\parallel} \right)$$

Measured solar wind proton velocity distributions

- Temperature anisotropies
- Ion beams
- Plasma instabilities
- Interplanetary heating

Plasma measurements made at 10 s resolution ($>0.29$ AU from the Sun)

Pilipp et al., JGR, 92, 1075, 1987

Set of reduced distribution functions

We can define an entire set of reduced distribution functions from $F$, for example the two-particle distribution function $f^{(2)}(x_1, v_1, x_2, v_2, t)$ by integrating $F(x_1, x_2, x_3, x_4, v_1, v_2, v_3, v_4, t)$ over coordinates and velocities of all but two particles:

$$\bar{n}_a \bar{n}_p f^{(2)}(x_1, v_1, x_2, v_2, t) = N_a N_p \int F \; dx_3 \ldots dx_N \; dv_3 \ldots dv_N$$

where $\alpha$ and $\gamma$ can be the same type or different species.

(Say describing the interaction of 2 electrons, 2 ions, or 1 ion and 1 electron)

Similar we can define the three-particle distribution function and so on.

Set of reduced equations

After integrating the Liouville equation we get the evolutionary equation for the one particle distribution function.

$$\frac{\partial f^{(1)}}{\partial t} + v_1 \cdot \frac{\partial f^{(1)}}{\partial x_1} + v_2 \cdot \frac{\partial f^{(1)}}{\partial x_2} + \cdots + v_N \cdot \frac{\partial f^{(1)}}{\partial x_N} = 0$$

We do not know the two particle distribution function! How can we derive it?

How to proceed?

- We integrate over the Liouville equation and get evolutionary equations for the reduced distribution functions.
- This reduces the number of dimensions from 6 N+1 to 7 for the one particle distribution function, 13 for the two-particle distribution function etc.

=> Derivation on the blackboard

Closed form

$$\frac{\partial f^{(1)}}{\partial t} \bigg|_{\text{particle}} = -\sum_{\beta} \bar{n}_\beta \int \psi_{\alpha \beta}(x_1, v_1, x_3, v_3) \cdot f^{(2)}(x_3, v_3, x_2, v_2, t) \; dx_3 \; dv_3$$

We reduced the high-dimensional (6N+1) Liouville equation to a set of equations for reduced distribution functions.
Set of reduced equations

- Problem: Equation for the one particle distribution function contains the two particle distribution function on the right side.
- In principle we know, how to derive that one: Do the corresponding integration over the Liouville equation (we do not show that explicitly in this lecture).
- Problem: Equation for the two particle distribution function contains the 3-particle distribution function on right side, and so on.

BBGKY-Hierarchy

- We must cut-off the hierarchy at some point.
- This means we make a suitable assumption for the term containing $f^{(n+1)}$, without computing it exactly.
- For a plasma we cut already after the first equation (for $f^{(1)}$) and make assumptions regarding $f^{(2)}$.

$$\Rightarrow \text{Kinetic Equations.}$$

- We have to simplify the term
  $$\sum_{\beta} \beta \int \frac{\partial}{\partial v_1} f^{(2)}(x_1, v_1, x_2, v_2, t) \, dx_2 \, dv_2$$

BBGKY-Hierarchy

(Bogoliubov,Born,Green,Kirkwood,Yvon)

The full set of these equations is equivalent to the Liouville-equation.

- Problem: Equation for $f^{(n)}$ contains $f^{(n+1)}$.
- ⇒ We cannot solve the full set of equations in the BBGKY-hierarchy. This is as complicated as solving the Liouville-equation directly.
- How to proceed?

Remark: This hierarchy of equations was first published in french by J. Yvon (1935), but this work was hardly recognized that time and got only attention after it was re-discovered in the end of the 1940th.

Kinetic Equations

- Particle interactions in a plasma are long range and we divide the particle interaction forces in:
  - Average force due to many distant particles.
  - Force due to nearest neighbours (Collisions).

- The average forces due to many distant particles do not depend on the exact position of these individual particles and we treat them together with the external forces.

$$\mathbf{a} = \mathbf{a}_{\text{ext}} + \langle \mathbf{a}_{\text{int}} \rangle$$

Vlasov Equation

$$\frac{\partial f_0^{(1)}}{\partial t} + \mathbf{v} \cdot \frac{\partial f_0^{(1)}}{\partial \mathbf{x}} + \frac{q}{m_0} \left( \mathbf{E} + \mathbf{v} \times \mathbf{B} \right) \cdot \frac{\partial f_0^{(1)}}{\partial \mathbf{v}} = 0$$

We get average fields $\langle \mathbf{E} \rangle$ and $\langle \mathbf{B} \rangle$ from Maxwell equations

$$\nabla \times \langle \mathbf{B} \rangle = \frac{\langle \rho \rangle}{\varepsilon_0}$$

$$\nabla \times \langle \mathbf{E} \rangle = \mu_0 \langle \mathbf{J} \rangle + \mu_0 \varepsilon_0 \frac{\partial \langle \mathbf{E} \rangle}{\partial t} = 0$$

How do we get the average charge density $\langle \rho \rangle$ and the average electric current $\langle \mathbf{J} \rangle$?

Simplest approach: Neglect the binary-collision rate. Only the average forces created by the other particles are considered ⇒ Collisionless plasma ⇒ Vlasov equation

Anatoly Vlasov (1908-1975)
The Vlasov equation expresses phase space density conservation. A 6D-volume element evolves like in an incompressible fluid.

**Vlasov Equation**
- We have actually to solve two Vlasov equations: for ions \( f^{(1)}_i \) and electrons \( f^{(1)}_e \).
- We write short \( f_i \) and \( f_e \) from now on and also \( x \) and \( v \) instead of \( x_1 \) and \( v_1 \).
- The fields \( (E) \) and \( (B) \) are of course unique and couple these two Vlasov equations.
- The average charge density \( \langle \rho \rangle \) and the average electric current \( (J) \) are only functions of the location and time, but not the velocity space.
- \( \langle \rho \rangle = \langle \rho_i \rangle + \langle \rho_e \rangle \), \( (J) = (J_i) + (J_e) \)
- We have to relate the macroscopic quantities \( \langle \rho \rangle (x,t) \) and \( (J(x,t)) \) to the distribution functions \( f_i(x,v,t) \) and \( f_e(x,v,t) \).

---

**Macroscopic variables of a plasma**
- We take moments of the distribution function \( f_\alpha \), where \( \alpha \) stands for ions and electrons. Moment means that we integrate in velocity space over quantities like
  \[
  \int v^n f_\alpha(x,v,t) \, dv
  \]
- Zero moment, densities (particle-, mass-, charge density):
  \[
  \begin{align*}
  n_\alpha(x,t) &= \bar{n}_\alpha \int f_\alpha(x,v,t) \, dv \\
  \rho_{m\alpha}(x,t) &= \bar{m}_\alpha \bar{n}_\alpha \int f_\alpha(x,v,t) \, dv \\
  \rho_{q\alpha}(x,t) &= \bar{q}_\alpha \bar{n}_\alpha \int f_\alpha(x,v,t) \, dv
  \end{align*}
  \]

---

**Macroscopic variables of a plasma**
- First moment (particle flux \( \Gamma \), macroscopic plasma flow \( \textbf{V}_\alpha \), electric current density \( J \)):
  \[
  \begin{align*}
  \Gamma_\alpha(x,t) &= \bar{n}_\alpha \int v \cdot f_\alpha(x,v,t) \, dv \\
  &= \bar{n}_\alpha(x,t) \textbf{V}_\alpha \\
  \textbf{V}_\alpha(x,t) &= \frac{\int v \cdot f_\alpha(x,v,t) \, dv}{\int f_\alpha(x,v,t) \, dv} \\
  J_\alpha(x,t) &= q_\alpha \bar{n}_\alpha \int v \cdot f_\alpha(x,v,t) \, dv \\
  &= q_\alpha \bar{n}_\alpha(x,t) \textbf{V}_\alpha(x,t)
  \end{align*}
  \]

---

**Macroscopic variables of a plasma**
- Second moment (Pressure Tensor \( P \), scalar pressure \( p \)):
  \[
  P_\alpha(x,t) = \bar{n}_\alpha m_\alpha \int (v - \textbf{V}_\alpha) \cdot (v - \textbf{V}_\alpha) f_\alpha(x,v,t) \, dv
  \]
- For spherical symmetric velocity distributions the pressure tensor becomes diagonal
  \[
  P_\alpha(x,t) = \begin{pmatrix}
  p_\alpha & 0 & 0 \\
  0 & p_\alpha & 0 \\
  0 & 0 & p_\alpha
  \end{pmatrix}
  \]
  with the scalar pressure
  \[
  p_\alpha(x,t) = \frac{\bar{n}_\alpha m_\alpha}{3} \int (v - \textbf{V}_\alpha)^2 f_\alpha(x,v,t) \, dv
  \]
  The assumption of a scalar pressure is popular for its simplicity, but not valid in some space plasmas like the solar wind. This leads to an anisotropic pressure tensor.

---

**Macroscopic variables of a plasma**
- Third moment (Heat flux \( H \)):
  \[
  H_\alpha(x,t) = \frac{\bar{n}_\alpha m_\alpha}{2} \int (v \cdot v) f_\alpha(x,v,t) \, dv
  \]
- It is possible to compute additional moments, but we cannot necessarily relate these higher moments to physical quantities.
- First and second moments are sufficient to close the Vlasov-Maxwell system.
- We can derive also equations for the derived macroscopic quantities. This leads to a fluid description of the plasma (like MHD) and we do that soon.
- In the following we continue to study the Vlasov-Maxwell system, kinetic equations and make more sophisticated approaches for collisions.
Vlasov-Maxwell Equations

kinetic description of a collisionless plasma

\[ \frac{\partial f_0}{\partial t} + \mathbf{v} \cdot \frac{\partial f_0}{\partial \mathbf{x}} + \frac{q_0}{m_0} (\mathbf{E} + \mathbf{v} \times \mathbf{B}) \cdot \frac{\partial f_0}{\partial \mathbf{v}} = 0 \]

\[ \nabla \cdot \mathbf{B} = 0 \]

\[ \nabla \cdot \mathbf{E} = \frac{1}{e_0} \sum \bar{n}_a q_a \int f_0 \, d\mathbf{v} + \frac{\rho_{\text{ext}}}{e_0} \]

\[ \nabla \times \mathbf{B} = \mu_0 \sum \bar{n}_a q_a \int \mathbf{v} f_0 \, d\mathbf{v} + \mu_0 e_0 \frac{\partial \mathbf{E}}{\partial t} + \mu_0 J_{\text{ext}} \]

\[ \nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t} \]

\( \alpha \) stands for ions and electrons.

Properties of Vlasov Equation

- Vlasov Equation conserves particles
- Distribution functions remains positive
- Vlasov equation has many equilibrium solutions

\[ \mathbf{v} \cdot \frac{\partial f_{\alpha 0}}{\partial \mathbf{x}} + \frac{q_0}{m_0} (\mathbf{E} + \mathbf{v} \times \mathbf{B}) \cdot \frac{\partial f_{\alpha 0}}{\partial \mathbf{v}} = 0 \]

Index 0 stands for equilibrium. Any distribution function \( f_{\alpha 0} \) which depends only on constants of motions (say \( a(x, v), b(x, v), \ldots \)) of the particle trajectories solves the stationary Vlasov equation. (show proof on blackboard)

\[ f_{\alpha 0}(x, v) = f_{\alpha 0}(a(x, v), b(x, v), \ldots) \]

Stability of Vlasov equilibria

- \( \frac{\partial f_{\alpha 0}}{\partial t} = 0 \) does not guaranty stability of \( f_{\alpha 0} \).
- Assume a nearby disturbed case \( f_{\alpha}(t) = f_{\alpha 0} + \delta f_{\alpha}(t) \)
- How does it develop with the time-dependent Vlasov-equation?
  - If \( \delta f_{\alpha}(t) \) decreases in time, the system will finally reach \( f_{\alpha 0} \Rightarrow \) Stable
  - If \( \delta f_{\alpha}(t) \) increases, the system will get further away from \( f_{\alpha 0} \Rightarrow \) Unstable
  - If \( f \) decreases monotonically with \( v^2 \) then the equilibrium is stable (Proof on blackboard):
  \[ \frac{\partial f}{\partial v^2} < 0 \]

Example: The well known Maxwell-Boltzmann-distribution

\[ f(v) \propto \exp \left( -\frac{m v^2}{2 k_b T} \right) \]

is stable!

(Proof on blackboard)

Further Examples

- Drifting Maxwellian?
  \[ f(v) \propto \exp \left( -\frac{m (v - u_p)^2}{2 k_b T} \right) \]

- Maxwellian with a non-thermal feature?
  \[ f(v) \propto \exp \left( -\frac{m v^2}{2 k_b T} \right) + \exp \left( -10 \cdot \frac{m (v - u_p)^2}{2 k_b T} \right) \]

Investigate stability as an exercise.

Kinetic equations of first order

\[ \frac{\partial f_{\alpha 0}^{(1)}}{\partial t} + \mathbf{v}_1 \cdot \frac{\partial f_{\alpha 0}^{(1)}}{\partial \mathbf{x}_1} + \frac{q_0}{m_0} (\mathbf{E} + \mathbf{v}_1 \times \mathbf{B}) \cdot \frac{\partial f_{\alpha 0}^{(1)}}{\partial \mathbf{v}_1} = \frac{\partial f_{\alpha 0}^{(1)}}{\partial t} |_{c} \]

where we get for the binary-collision rate

\[ \frac{\partial f_{\alpha 0}^{(1)}}{\partial t} |_{c} = -\sum_{\beta} (a_{\alpha \beta} - (a_{\alpha \beta}^{(1)}) \frac{\partial f_{\alpha 0}^{(1)}}{\partial \mathbf{v}_1}(x_1, v_1, x_2, v_2, t) \, dx_2 \, dv_2 \]

- Vlasov approach: neglect 2 particle distribution function completely
- Now we make a more sophisticated approach, the Mayer cluster expansion.
**Mayer cluster expansion**

\[
f^{(2)}_{\alpha,\beta} = g^{(1)}_{\alpha,\beta}(x_\alpha, v_\alpha, 0) f^{(1)}_{\beta}(x_\beta, v_\beta, 0) + g^{(2)}_{\alpha,\beta}(x_\alpha, x_\beta, v_\alpha, v_\beta, 0)
\]

- Particles are independent from each other
- Correlation of the 2 particles

In Vlasov theory we assumed \( g^{(2)}_{\alpha,\beta} = 0 \), which means that the single particle distribution functions are uncorrelated.

We take now correlations into account, but assume

\[
g^{(2)}_{\alpha,\beta} \ll f^{(1)}_{\alpha} f^{(1)}_{\beta}
\]

This is a valid assumption, because in a small volume

\[
V \ll \lambda_D^3
\]

The joint distribution function \( f^{(2)}_{\alpha,\beta} \) is determined by the many particles outside \( V \) and not by the separation of two particle from each other.

**Collisions**

Plasmas may be **collisional** (e.g., fusion plasma) or **collisionless** (e.g., solar wind). Space plasmas are usually collisionless. => Vlasov equation

**Ionization state of a plasma:**

- **Partially ionized:** Earth’s ionosphere or Sun’s photosphere and chromosphere, dusty and cometary plasmas
  => Collisions with neutrals dominate
- **Fully ionized:** Sun’s corona and solar wind and most of the planetary magnetospheres
  => Coulomb collisions or collisionless

**Coulomb collisions**

Charged particles interact via the Coulomb force over distances much larger than atomic radii, which enhances the cross section as compared to hard sphere collisions, but leads to a preference of small-angle deflections.

Impact or collision parameter, \( d_{ei} \) and scattering angle, \( \gamma_c \)

\[
\nu_{ei} = n_e \sigma_e(v_e)
\]

**Models for the collision terms**

Neutral-ion collisions are described by a Maxwell-Boltzmann collision terms as in Gas-dynamics. \( f_n \) : distribution function of neutrals, \( \nu_i \) collision frequency:

\[
\begin{align*}
\frac{\partial f}{\partial t} &= \nu_n (f_n - f) \\
\frac{\partial f}{\partial t} &= \nabla \cdot (D \cdot \nabla f)
\end{align*}
\]

Further sophistications are to take into account that Coulomb collisions occur not in vacuum, but are Debye-shielded and to consider wave-particle interactions.

**Kinetic Equations**

- In Kinetic theory we have a statistic description in a 6D phase space (configuration and velocity space).
- Kinetic equations are a first order approximation of the BBGKY-Hierarchy.
- Equation for Particle distribution function is coupled with Maxwell-equations => Difficult to solve.
- Most space plasmas are collisionless => Vlasov equation
- Collision terms depend on nature of process:
  - collision with neutrals => Maxwell-Boltzmann
  - Coulomb collisions: Fokker-Planck
  - Coulomb c. with Debye-shielding => Lennard Balescu

**How to proceed?**

- Due to the nonlinear coupling with Maxwell-equations, the kinetic equations are difficult to solve.
- In numerical simulations one has to resolve relevant plasma scales like Debye-length, gyro-radii of electrons and ions and also the corresponding temporal scales (gyro-frequencies, plasma frequencies), which are orders of magnitude smaller and faster as the macroscopic scales (size of magnetosphere or active region)
- We often not interested in details of the velocity distribution function.
- => Integration over the velocity space lead to fluid equations like MHD (3D instead of 6D space)
